(2) Horticultural Research Institute, ARC.

### Summary

Fourteen cultivars/clones of sweetpotato were delivered to AGERI from International Potato Center (CIP)/Nirobi in 2002 as cuttings. They were *in vitro* propagated for their massive micro-propagation. Different media compositions and incubation conditions were examined to determine the optimal conditions for each cultivar. *In vitro* plants were acclimatized under insect–proof greenhouse and used as mother plants for the cuttings to be evaluated at the AGERI experimental field as well as at Kafr El Zayat location. Plants were harvested. Yield was evaluated on bases of weight and number of roots. Eight cultivars and lines have promising yield productivity under Egyptian conditions.

#### Introduction

Sweetpotato (*Ipomoea batatas* L.), is one of the most important tuber crops worldwide. It has a diverse range of positive characteristics including high yield per unit area, nutritional value, and resistance to several production stresses (Kays, 2005)

Orange-fleshed Sweetpotato cultivars are rich in B-carotene that is the precursor of vitamin A. Its deficiency results in slow development, stunted growth, night blindness and total blindness. In Africa, 250 million children suffer from vitamin A deficiency, VAD, One third of pre-school children have manifold health problems due to VAD. In Egypt, VAD is prevalent among 0.6% of pre-school children and 0.4% of their mothers (Anonymous, 1995). In Egypt, the area of Sweetpotato under production has reached 30.000 acre. The average yield is 12 tons per acre.

#### **Materials and Methods**

• Forteen cultivars/clones of sweetpotato (Table 1) were delivered to AGERI from CIP/ Nirobi in 2002 as 20 cuttings for each cultivar/clone.

• Clones were return to *in vitro* propagation for their massive micro-propagation (Fig. 1).

• Different media compositions (MS basal salt media and 2-4% sucrose supplemented with several concentrations of 0.1, 0.5 and 1.0 mg/l BA and/or kinetin, in combination with 0.5 mg/l GA<sub>3</sub> or IAA) were tested. Plants were incubated at  $24^{\circ}$ C- $30^{\circ}$ C under 16 hours of light with intense ranged from 200-500 foot candle.

• *In vitro* plants were acclimatized under insect–proof greenhouse and used as mother plants for the cuttings to be evaluated at the AGERI experimental field (clay heavy soil) as well as Kafr El Zayat location (sandy loamy soil, Fig.2).

• Plants were harvested over 3 times (130, 150 and 170 days).

• Yield characteristics (weight of roots and number of roots) were evaluated (Table, 2 and 3)

• Based on field evaluation results, 8 cultivars were selected to be evaluated for their chemical composition (total soliable solids (TSS), total solids (TS), ascorbic acid. total carotenoieds. moisture. total protein, protein digestibility, lipids, reducing sugars, root fiber, ash, carbohydrates, starch and minerals (Zn, Mn, Fe, Ca, Na, and K), in collaboration with the Food

Technology Research Institute (FTRI), ARC.

### Results

- MS media supplemented with 0.4% sucrose with 0.5 mg/l GA<sub>3</sub> was the best selected media under incubation conditions of 28°C and 375-400 foot candles for all tested cultivars.
- Field evaluation indicated that cultivars/clones Beauregard, Tainung-64, Gemsa-74-228, NC-1525, Japon Transmesion, Kemb-37, Santo Amaro and Lo-323 were promising in production and root quality (Fig. 3).

## Acknowledgment

The authors would like to thank the International Potato Center, CIP, for providing the sweetpotato germplasm used in this study.
